

# A Formal Verification of Reversible Primitive Permutations

Giacomo Maletto

# 1. The definition

## 1.1 Reversible computing

Reversible computing is a model of computation in which every process can be run backwards. Simply put, in a reversible setting any program takes inputs and gives outputs (like usual), but can also go the other way around: provided the output it can reconstruct the input. In a mathematical sense, every function is expected to be invertible.

Why do we care about such a thing?

Firstly, having a programming language in which every function (or even a subset of functions) is reversible could lead to interesting and practical applications.

But we can also imagine reversible computers, in which the underlying architecture is inherently reversible: Toffoli gates provides a way to do so. The opposite of reversibility is loss of information, which (for thermodynamic reasons) leads to loss of energy and heat dissipation. This means that a non-reversible gate dissipates energy each time information is discarded, while in principle a reversible computer wouldn't.

Lastly, reversible computing is directly related to quantum computing, as each operation in a quantum computer must be reversible.

## 1.2 Reversible Primitive Permutations

In the article I decided to formalize, the authors focus on providing a functional model of reversible computation. They develop an inductively defined set of functions, called **Reversible Primitive Permutations** or **RPP**, which are expressive enough to represent all Primitive Recursive Functions (we talk about what this means in section ?). Here is the definition that we will use:

**Definition 1.2.1** (Reversible Primitive Permutations).

The class of **Reversible Primitive Permutations** or RPP is the smallest subset of functions  $\mathbb{Z}^n \rightarrow \mathbb{Z}^n$  satisfying the following conditions:

- The **identity**  $\text{Id}(x) = x$  belongs to RPP.

$$x \quad \text{Id} \quad x$$

- The **sign-change**  $\text{Ne}(x) = -x$  belongs to RPP.

$$x \quad \text{Ne} \quad -x$$

- The **successor function**  $\text{Su}(x) = x + 1$  belongs to RPP.

$$x \quad \text{Su} \quad x + 1$$

- The **predecessor function**  $\text{Pr}(x) = x - 1$  belongs to RPP.

$$x \quad \text{Pr} \quad x - 1$$

- The **swap**  $\text{Sw}(x, y) = (y, x)$  belongs to RPP.

$$\begin{array}{ccc} x & & y \\ y & \text{Sw} & x \end{array}$$

- If  $f : \mathbb{Z}^n \rightarrow \mathbb{Z}^n$  and  $g : \mathbb{Z}^n \rightarrow \mathbb{Z}^n$  belongs to RPP, then the **series composition**  $(f \circ g) : \mathbb{Z}^n \rightarrow \mathbb{Z}^n$  belongs to RPP and is such that:

$$(f \circ g)(x_1, \dots, x_n) = g(f(x_1, \dots, x_n)) = (g \circ f)(x_1, \dots, x_n).$$

We remark that  $f \circ g$  means that  $f$  is applied first, and then  $g$ , in opposition to the standard functional composition (denoted by  $\circ$ ).

$$\begin{array}{ccc} x_1 & & y_1 \\ \vdots & & \vdots \\ x_n & f \circ g & y_n \end{array} = \begin{array}{ccc} x_1 & & y_1 \\ \vdots & f & \vdots \\ x_n & g & y_n \end{array}$$

- If  $f : \mathbb{Z}^n \rightarrow \mathbb{Z}^n$  and  $g : \mathbb{Z}^m \rightarrow \mathbb{Z}^m$  belongs to RPP, then the **parallel composition**  $(f \parallel g) : \mathbb{Z}^{n+m} \rightarrow \mathbb{Z}^{n+m}$  belongs to RPP and is such that:

$$(f \parallel g)(x_1, \dots, x_n, y_1, \dots, y_m) = (f(x_1, \dots, x_n), g(y_1, \dots, y_m)).$$

$$\begin{array}{ccc} x_1 & & w_1 \\ \vdots & & \vdots \\ x_n & & w_n \\ y_1 & & z_1 \\ \vdots & & \vdots \\ y_m & & z_m \end{array} \quad f \parallel g = \begin{array}{ccc} x_1 & & w_1 \\ \vdots & f & \vdots \\ x_n & & w_n \\ y_1 & & z_1 \\ \vdots & g & \vdots \\ y_m & & z_m \end{array}$$

- If  $f : \mathbb{Z}^n \rightarrow \mathbb{Z}^n$  belongs to RPP, then the **finite iteration**  $\text{It}[f] : \mathbb{Z}^{n+1} \rightarrow \mathbb{Z}^{n+1}$  belongs to RPP and is such that:

$$\text{It}[f](x, x_1, \dots, x_n) = (x, \overbrace{(f \circ \dots \circ f)}^{\downarrow x \text{ times}}(x_1, \dots, x_n))$$

where  $\downarrow(\cdot) : \mathbb{Z} \rightarrow \mathbb{N}$  is defined as

$$\downarrow x = \begin{cases} x, & \text{if } x \geq 0 \\ 0, & \text{if } x < 0 \end{cases}.$$

This means that the function  $f$  is applied  $\downarrow x$  times to  $(x_1, \dots, x_n)$ .

$$\begin{array}{c} x \\ x_1 \\ \vdots \\ x_n \end{array} \begin{array}{|c|} \hline \text{It}[f] \\ \hline \end{array} \begin{array}{c} x \\ y_1 \\ \vdots \\ y_n \end{array} = \begin{array}{c} x \\ x_1 \\ \vdots \\ x_n \end{array} \underbrace{\begin{array}{|c|} \hline f \\ \hline \end{array} \dots \begin{array}{|c|} \hline f \\ \hline \end{array}}_{\downarrow x \text{ times}} \begin{array}{c} x \\ y_1 \\ \vdots \\ y_n \end{array}$$

- If  $f, g, h : \mathbb{Z}^n \rightarrow \mathbb{Z}^n$  belongs to RPP, then the **selection**  $\text{If}[f, g, h] : \mathbb{Z}^{n+1} \rightarrow \mathbb{Z}^{n+1}$  belongs to RPP and is such that:

$$\text{If}[f, g, h](x, x_1, \dots, x_n) = \begin{cases} (x, f(x_1, \dots, x_n)), & \text{if } x > 0 \\ (x, g(x_1, \dots, x_n)), & \text{if } x = 0 \\ (x, h(x_1, \dots, x_n)), & \text{if } x < 0 \end{cases}.$$

We remark that the argument  $x$  which determines which among  $f$ ,  $g$  and  $h$  must be used cannot be among the arguments of  $f$ ,  $g$  and  $h$ , as that would break reversibility.

$$\begin{array}{c} x \\ x_1 \\ \vdots \\ x_n \end{array} \begin{array}{|c|} \hline \text{If}[f, g, h] \\ \hline \end{array} \begin{array}{c} x \\ y_1 \\ \vdots \\ y_n \end{array} \left\} = \begin{cases} f(x_1, \dots, x_n) & \text{if } x > 0 \\ g(x_1, \dots, x_n) & \text{if } x = 0 \\ h(x_1, \dots, x_n) & \text{if } x < 0 \end{cases}$$
